

Observation and analysis of the modal component at gSamp

Posterior disturbance probability, marginalized over tau

$\log O_t = \log(\text{betaPlus} / \text{beta}_0) + \log \text{BF}_t$

$$z = (y_t - H \mu_f) / \sqrt{H \text{Sig}_f H' + R}, \text{ best branch per class}$$

z per component, shaded by posterior weight $\alpha[j,k]$

Predictive sd $\sqrt{H \text{ Sig}_f H' + R}$ by class

Posterior mass by class at gSamp

Relative pull of each factor toward disturbance

Which factor gives the modal disturbed component its weight

Relative influence of wPrev, beta and likelihood

Likelihood term: spread advantage vs centring advantage

wPrev[t, g, 2]: mean and ± 1 sd across the tau grid

$I[2,0] / I[1,0]$ against the threshold γ_1 / γ_2
